(57) **ABSTRACT**

An information processing system includes an information management apparatus that accepts image generation requests and an image generation section that generates image data, which is provided independently of the information management apparatus. The information management apparatus issues a job ID in response to a print request from a client, and transmits the job ID and a URL of the image generation apparatus to the client. Based on the URL, the client directly requests the image generation apparatus for image data corresponding to the job ID.

# GENERATING IMAGE DATA IN ACCORDANCE WITH IDENTIFICATION INFORMATION

## CROSS REFERDNCE TO RELATED APPLICATION

The present application is a continuation of U.S. patent application Ser. No. 13/892,963, filed May. 13, 2013, which is a continuation of U.S. patent application Ser. No. 13/182,043, filed Jul. 13, 2003, now U.S. Pat. No. 8,456,683, issued Jun. 4, 2013, which is a continuation of U.S. patent application Ser. No. 10/370,354, filed Feb. 18, 2003, now U.S. Pat. No. 8,004,701 on Aug. 23, 2011. The entire disclosures these earlier applications are hereby incorporated by reference herein.

## BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to information processing systems, information processing apparatuses, information processing methods and programs.

2. Related Background Art

Accompanied by rapid development of the Internet and deployment of a large number of Web servers, more and more business transactions are conducted on the Web. By simply installing Web browsers that are capable of displaying and entering information on personal computers that are connected to the network, business transactions can be widely conducted through the Web browsers. Also, a Web server is present on the network in order to conduct business through Web browsers. Information is exchanged between the Web server and Web browsers that are clients. The Web server repeats necessary operations, such as, receiving information entered through the Web browsers, processing the information, and sending the processed results to the Web browsers. As a result, the users obtain the results of the data processing, and conduct the business.

With respect to printing processing, the following system is provided: the server executes an overlay processing using form data (template data) based on s print request that has been sent from a client, and delivers data that provides fine print results to the client.

However, in the printing processing that is conducted through Web browsers in the conventional system, a single control section is entirely responsible for accepting image generation requests from clients, controlling execution of image generation, and controlling delivery of generated slip image data.

In the Web system that is essentially asynchronously operated, management of all of these controls by a single control section makes the system more complex, statuses and data transfer states more difficult to be understood by the users, and the system management such as error handling processing more difficult.

## SUMMARY OF THE INVENTION

The present invention has been made in view of the problems described above, and relates to a system in which acceptance of image generation requests by a request control section and generation of image data by an image generation section are separated from each other and independently controlled, and clients directly obtain generated image data from the image generation section. As a result, the request control section can devote its control to management of statuses of image data generation processing, and the processing load can be distributed between the request control section and the image generation section. In one embodiment, a plurality of image generation sections may be provided on individual apparatuses, and image data generation processings may be executed in parallel on the plurality of image generation sections.

Also, an embodiment of the present invention provides a device that allows clients to directly obtain image data from the image generation section.

Further, in accordance with another embodiment of the present invention, image data generation processings are managed by using job IDs that are unique in the system such that the status management is facilitated, and the progress of data generation processings in response to each image generation request can be readily grasped.

Other features and advantages of the invention will be apparent from the following detailed description, taken in conjunction with the accompanying drawings that illustrate, by way of example, various features of embodiments of the invention.

## BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** is a block diagram of a exemplary structure of a network printing system.

FIG. **2** shows a flowchart of processings performed by a request control apparatus to generate data for obtaining images.

FIG. **3** shows an example of a composition of an address list of an image generation apparatus.

FIG. **4** shows an example of a composition of a table for managing job IDs.

FIG. **5** shows contents of an image obtaining request.

FIG. **6** is a flowchart of processings performed by a client to transmit an image obtaining request.

FIG. **7** is a flowchart of processings performed by an image generation apparatus to generate image data and transmit the image data to a client.

FIG. **8** is a flowchart of processing performed by a client to print the image data received.

FIG. **9** is a flowchart of processing performed by a request control apparatus to generate data for obtaining images.

FIG. **10** is a flowchart of processings performed by an image generation apparatus to generate image data.

FIG. **11** is a flowchart of processings performed by an image generation apparatus to transmit image data to a client.

FIG. **12** shows a status management table.

## DESCRIPTION OF PREFERRED EMBODIMENTS

An embodiment of the present invention is described below in detail with reference to the accompanying drawings.

FIG. **1** is a block diagram of a functional structure of a network print system that is a data processing system (e.g., an image generation system) in accordance with an embodiment of the present invention. The network print system includes a client apparatus **101** (hereafter referred to as a "client"). The client **101** may be composed of an information processing apparatus, such as, for example, a personal computer, a work station, a portable information processing console, a portable data assistants (PDA), a host computer, or the like. A request generation section **102** generates s image generation requests in response to instructions by the user. An application **108** provides inputs and outputs in and from a server, and may include a Web browser. The, application **103** has a function to

transmit requests generated by the request generation section **102** and send the generated requests to the server, as well as a function to transmit requests w for obtaining image data (which may also be referred to as "image data obtaining requests" below) to designated image generation apparatuses based on job IDs issued by the server, and a function to send image data received to a print output section **104**. The print output section **104** converts the image data received into a format that can be outputted by a printer **105** connected to the print output section **104**. The print output section **104** may be a printer driver.

A network **106** connects a request control apparatus **109** and the client **101**. The network **106** can be any type of network that can accommodate communication procedures of the Web environments, such as, LAN, the Internet, wireless communication and the like. A network **107** connects an image generation apparatus **112** and the client **101**. The network **107** may have a similar configuration as that of the network **106**. A network **108** connects another image generation apparatus and the client **101** like the network **107**. By the networks **107** and **108**, the client is connected to a plurality of image generation apparatuses. In FIG. **1**, the networks **106**, **107** and **108** are shown independently from one another, but they can be composed of a single network. Also, the networks **106**, **107** and **108** and another network **122** (to be described below) may be composed of a single network.

The request control apparatus **109** may be composed of an information processing apparatus, such as, for example, a personal computer, a work station, a portable information processing console, a portable data assistants (PDA), a host computer, or the like. A network communication section **110** plays a role of at least a part of a Web server. A request control section **111** may be implemented as a part of the Web server, and issues job IDs in response to image generation requests from the client, and controls and manages all requests in the system.

The image generation apparatus **112** may be composed of an information processing apparatus, such as, for example, a personal computer, a work station, a portable information processing console, a portable data assistants (PDA), a host computer, or the like. A network communication section **113** is provided at the image generation apparatus **112**. In other words, the image generation apparatus itself has a function of a Web server. An image generation section **114** generates slip image data according to stipulated formats. Image data may be raster image data or vector image data. A slip form storage section **115** stores slip forms that are necessary for generating images. A data storage section **116** stores data such as a data base including various business data. An image generation apparatus **117** that is similar to the image generation apparatus **112** is also connected to the client **101**. This means that the system of the present embodiment includes a plurality of image generation apparatuses. The plurality of image generation apparatuses are provided independently of one another and may be operated independently, in a linked manner or in parallel with one another. The image generation apparatus **117** is provided with a network communication section **118**, an image generation section **119**, a slip form storage section **120** and a data storage section **121**, which are similar to the network communication section **118**, the image generation section **114**, the slip form storage section **115** and the data storage section **116** provided at the image generation apparatus **112**. The request control apparatus **109** and the image generation apparatuses **112** and **117** are connected via a network **122**.

<Generation of Job IDs>

FIG. **2** shows a flowchart of processings performed by the request control apparatus **109** to generate data for obtaining images upon receiving a print request from the client **101**.

First in step **201**, an HTTP request received through a browser or the like is analyzed; and in step **202**, data necessary for generating images are specified. The data necessary for generating images may be data that is inputted by the user at the client, or data that is read from the data storage section **116**. Then in step **208**, slip form data necessary for generating images (slip template data) is specified. In step **204**, printer information at the time of executing prints and print conditions such as the number of prints are specified.

In step **205**, an ID (identification information) for identifying the print request, which is unique within the system, is generated for the information specified in step **202** through step **204**, and stored in a table as a job ID corresponding to the print request.

In step **206**, an appropriate image generation apparatus is selected based on image generation apparatus information concerning image generation apparatuses that are in operation. In step **207**, an address list (to be described below) of a URL of the selected image generation apparatus is obtained. In step **208**, an image obtaining request data is created by combining the obtained URL and the job ID.

In step **209**, the generated image obtaining request data is transmitted to the client. Then, processings at the client side are performed as indicated at **210** (processings in FIG. **8**).

FIG. **3** shows an address list **301** of image generation apparatuses, which is retained and managed by the request control apparatus **109**. The address list **301** stores host computer names (hereafter called as "host names") that identify a plurality of corresponding image generation apparatuses and URLs (Uniform Resource Locators) that are addresses of the corresponding image generation apparatuses. Beside URLs, other addresses, such as, for example, IP (Internet Protocol) addresses that are used in a network may also be used as addresses of the image generation apparatuses.

The address **301** includes multiple host names Host **1**, Host **2**, . . . Host n (**302**, **304**, . . . **306**), and URLs URL **1**, URL **2**, . . . URLn (**303**, **305**, . . . **307**) corresponding to the host names Host **1**, Host **2**, . . . Host n, respectively.

When a host computer on the system starts as an image generation apparatus, the host computer notifies the request control apparatus **109** of its host name and URL, and the request control apparatus **109** stores the information (host name and URL) in the address list **301**.

FIG. **4** shows a table **401** for managing job IDs. This table is stored in the request control apparatus **109**. The table **401** stores data necessary of image generation, slip form data, combinations of print conditions for each of a plurality of job IDs. The request control apparatus **109** stores in this table data specified or generated through steps **202** through **205**.

For example, the table **401** stores a job ID **402** that is generated in step **205** in response to a specified print request, and a data set **403** corresponding to the job ID **404**, which includes data specified through steps **202**-**204**, slip form data and print conditions. The data set **408** may store data itself, or anything that indicates a place where data is stored, such as an address of the data stored.

A job ID **404** is generated in response to a print request that is different from the print request for the job ID **402**. A data set **405** includes data, slip form data and print conditions corresponding to the job ID **404**. The data set **406** indicates that a plurality of slip forms (i.e., Slip **1** and Slip **2**) are required. FIG. **4** indicates that a plurality of job IDs, Job ID **1**, Job ID**2**, . . . Job IDn (**402**, **404**, . . . **406**), and data sets

containing data, slip form data and print conditions corresponding to the respective job IDs are registered in the table **401**.

FIG. **5** shows contents of image obtaining request data **501** that is generated in step **206**. The image obtaining request data **501** contains a job ID **502** that is generated in step **205** in response to a request that is received in step **201**, and a URL **503** of an image generation apparatus that generates image data for the print request indicated by the job ID **502**. The request control apparatus **109** preferentially detects, among the plurality of image generation apparatuses under its management, an image generation apparatus that has an allowance for image generation processing capacity, obtains an URL of the detected image generation apparatus from the address list **301**, and stores the obtained URL in the image obtaining request data **501**.

<Obtaining Image Data>

FIG. **6** is a flowchart of processings in which the client **101** that has received the image obtaining request data from the request control apparatus **109** transmits an image obtaining request based on the image obtaining request data to the image generation apparatus. The processings shown in FIG. **6** continue from the processings in FIG. **2** indicated at **601**. In step **602**, the client **101** receives the image obtaining request data that has been transmitted from the request control apparatus **109** in step **207**. In step **603**, the client **101** directly transmits to the designated image generation apparatus an image obtaining request based on the job ID and URL that are indicated in the received image obtaining request data. At this time, the job ID is transmitted with the image obtaining request. The processings shown in FIG. **6** continue to processings indicated at **604** that are performed on the image generation apparatus side (see FIG. **7**).

FIG. **7** is a flowchart of processings in which the image generation apparatus that receives the image obtaining request from the client **101** generates image data and transmits the generated image data to the client **101**. The processings shown in FIG. **7** continue from the processings in FIG. **6** indicated at **701**.

In step **702**, the image generation apparatus receives the image obtaining request that has been transmitted from the client **101** in step **603**. In step **703**, based on the job ID received together with the image obtaining request, a corresponding job ID is searched from the table **401** that is managed by the request control apparatus **109**, and data necessary for image generation, slip form data and print conditions corresponding to the job ID are obtained from the request control apparatus **109**. More specifically, to obtain these data sets, the image generation apparatus transmits the job ID to the request control apparatus **109** and requests a search; and the request control apparatus **109** retrieves a corresponding job ID, and transmits data sets detected as a result of the search to the image generation apparatus.

In step **704**, image data is generated based on the data sets obtained in step **703**. For example, image data is generated by combining the data necessary for image generation and the slip form data, and further the image data is edited to meet the printing conditions.

In step **705**, the image data generated in step **704** is transmitted to the client **101** as a response to the image obtaining request. The processings in FIG. **7** continue to processings indicated at **706** on the side of the client **101** (processings shown in FIG. **8**).

FIG. **8** is a flowchart of processings in which the client **101** controls printing based on the image data received from the image generation apparatus. The processings shown in FIG. **8** continue from the processings in FIG. **7** indicated at **801**.

In step **802**, the client **101** receives the image data that has been transmitted from the image generation apparatus in step **705**. In step **803** the print output section **104** converts the image data received into data in a printable format, and the converted data is transferred to the printer **105** where the data is printed.

The image generation apparatuses are equipped with the network communication control sections **118** and **118**, respectively, such that each of the image generation apparatuses has a function of a Web server. In the conventional system, when a client sends a print request to a Web server that solely exists in the system, sessions with the server need to be maintained until image data is obtained. However, in one aspect. In the system in accordance with the present embodiment, a client transmits a print request and an image obtaining request with independent HTTP requests to different apparatuses, as indicated in step **201** and step **702**. For this reason, the time for maintaining sessions with the Web server can be shortened. Furthermore, since the request control apparatus and the image generation apparatus are separated from each other, the processing load is distributed between them.

Also, as indicated in step **205**, a unique job ID is allocated to each print request. Therefore, even when a plurality of print requests occur, the client can obtain proper image data, and can clearly grasp the processing progress for each print request.

In the description above, the image generation apparatus starts creating image data in response to an image obtaining request from the client. However, the system may be arranged such that image data may be generated before an image obtaining request is received from a so that image data can be promptly transmitted to the client.

FIG. **9** shows a flowchart of processings which include steps **901** and **902** added to the processings in FIG. **2**. In step **901**, the request control apparatus **109** transmits an image data generation request to a selected image generation apparatus. At this time, a job ID generated in step **205** and data sets specified in steps **202-204** are transmitted together with the image data generation request to the selected image generation apparatus.

In step **902**, the job ID and a host name of the selected image generation apparatus are registered in a status management table. Also, a status "Being Generated" is also registered.

FIG. **12** shows an example of a statue management table **1201** that is retained and managed by the request control apparatus **109**. The statue management table **1201** stores a host name of an image generation apparatus that generates image data corresponding to a job ID, and a progress status of generating data corresponding to the job ID for each of a plurality of job IDs. Columns **1202**, **1203** and **1204** of the statue management table **1201** indicate job IDs, host names and progress statuses, respectively.

For example, a row **1205** of the status management table **1201** indicates that image data corresponding to a print request whose job ID is "1" has already been generated by an image generation apparatus whose host name is "Host **1**".

The request control apparatus **109**, in response to a status request from the client **101**, returns to the client **101** information (host name and status information) corresponding to the job ID that is designated by the status request. By so doing, the client **101** can grasp the progress status of an image generation processing for the print request.

FIG. **10** is a flowchart of processings in which the image generation apparatus that has received the image data generation request from the request control apparatus **109** generates

image data, and stores the generated image data. The processings shown in FIG. **10** continue from the processings In FIG. **9** indicated at **1001**.

In step **1002**, the image generation apparatus receives the image data generation request that has been sent from the request control apparatus **109** in step **601**. In step **1003**, the image generation apparatus obtains the job ID, data necessary for image generation, slip form data and print conditions received together with the image data generation request.

In step **1004**, image data is generated based on the data obtained in step **1003**. For example, image data is generated by combining the data necessary for image generation and the slip form data, and further the image data is edited to meet the printing conditions.

In step **1005**, the image data generated in step **104** is correlated to the job ID and stored in the image data memory. In step **1006**, completion of generating the image data together with the job ID is notified to the request control apparatus **109**.

The request control apparatus **109**, in response to the notice of completion of generating the image data, registers a status "Generation Completed" in the statue management table.

FIG. **11** is a flowchart of processings similar to those shown in FIG. **7** except that step **703** in FIG. **7** is deleted, and step **704** in FIG. **7** is modified. In step **1104**, the image generation apparatus searches image data corresponding to the job ID from the image data memory based on the job ID received together with the image obtaining request. Then, in step **705**, the image data detected as a result of the search is transmitted to the client **101**.

As a result, the image generation apparatus can return image data quicker in response to an image obtaining request from a client.

The present invention can be achieved by having a storage medium that stores program codes of software that realize the functions of tho embodiments described above supplied to a system or an apparatus, and by having a computer (or a CPU or an MPU) of the system or the apparatus read and execute the program codes stored in the storage medium.

In this case, the program codes themselves that are read from the storage medium realize the functions of the embodiment of the present invention, and the storage medium that stores the program codes constitute the present invention.

The storage medium to supply the program codes may be a flexible disk, a hard disk, an optical disk, an optical magnetic disk, a CD-ROM, a CD-R, a CD-RW, a magnetic tape, a nonvolatile memory card or a ROM.

Furthermore, the present invention is applicable not only when the program codes read by a computer are executed to realize the functions of the embodiments, but also when an operating system that operates on the computer performs a part or all of the actual processing based on the instructions contained in the program codes and thereby realizes the functions of the embodiments.

Moreover, the present invention is also applicable when the program codes that are read from the storage medium are written on a memory of an expansion board inserted into a computer or of an expansion unit connected to a computer, and a CPU provided on the expansion board or on the expansion unit performs a part or all of the actual processing based on the instructions contained in the program codes and thereby realizes the functions of the embodiments.

It is clear froth the description above that, in accordance with the present invention, an information processing apparatus that accepts print requests and an image generation apparatus that generates image data can be provided independently from each other on the system, such that the processing load can be distributed. Also by this system, a plurality of image generation apparatuses can be provided cm the system, and image data generation processings can be executed in parallel with one another.

Further, identification information to identify print requests is managed by the system in accordance with the present invention, such that statuses of print processing for individual print requests can be readily grasped.

While the description above rams to particular embodiments of the present invention, it will be understood that many modifications may be made without departing from the spirit thereof. The accompanying claims are intended to cover such modifications as would fall within the true scope and spirit of the present invention.

The presently disclosed embodiments are therefore to be considered in all respects as illustrative and not restrictive, the scope of the invention being indicated by the appended claims, rather than the foregoing description, and all changes which come within the meaning and range of equivalency of the claims are therefore intended to be embraced therein.

What is claimed is:

**1**. A system which includes an information management apparatus, an information processing apparatus and an image generation apparatus, wherein:

the information processing apparatus comprises a first transmission unit configured to transmit content;

the information management apparatus comprises

a first generation unit configured to generate identification information corresponding to the content, according to a request by the information processing apparatus, and

a second transmission unit configured to transmit the identification information generated by the first generation unit to the information processing apparatus;

the information processing apparatus further comprises a third transmission unit configured to transmit the identification information received from the information management apparatus to the image generation apparatus; and

the image generation apparatus comprises

a fourth transmission unit configured to transmit the identification information received from the information processing apparatus,

an obtaining unit configured to obtain content corresponding to the identification information, and

a second generation unit configured to generate image data for printing based on the content obtained by the obtaining unit.

**2**. The system according to claim **1**, wherein

the information management apparatus further comprises a receiving unit configured to receive data to be used for printing processing, from the information processing apparatus, and

the second transmission unit of the information management apparatus transmits the identification information to the information processing apparatus if the data to be used for the printing processing is received.

**3**. The system according to claim **1**, wherein the second transmission unit of the information management apparatus transmits the identification information and an address of the image generation apparatus to the information processing apparatus.

**4**. The system according to claim **1**, wherein the image generation apparatus further comprises a combining unit configured to combine the image data for printing and form data with each other.

**5**. The system according to claim **1**, wherein the image data for printing is data to be printed.

6. The system according to claim 1, wherein

the fourth transmission unit of the image generation apparatus transmits the identification information received from the information processing apparatus to the information management apparatus, and

the obtaining unit of the image generation apparatus obtains the content related to the identification information from the information management apparatus.

7. A controlling method for a system including an information management apparatus, an information processing apparatus which performs a first transmission step of transmitting content, and an image generation apparatus, comprising:

causing the information management apparatus to perform

a first generation step of generating identification information corresponding to the content, according to a request by the information processing apparatus, and

a second transmission step of transmitting the identification information generated in the first generation step to the information processing apparatus;

causing the information processing apparatus further to perform a third transmission step of transmitting the identification information received from the information management apparatus to the image generation apparatus; and

causing the image generation apparatus to perform

a fourth transmission step of transmitting the identification information received from the information processing apparatus,

an obtaining step of obtaining content corresponding to the identification information, and

a second generation step of generating image data for printing based on the content obtained in the obtaining step.

8. The controlling method according to claim 7, wherein

the controlling method further causes the information management apparatus to perform a receiving step of receiving data to be used for printing processing, from the information processing apparatus, and

the second transmission step in the information management apparatus transmits the identification information to the information processing apparatus if the data to be used for the printing processing is received.

9. The controlling method according to claim 7, wherein the second transmission step in the information management apparatus transmits the identification information and an address of the image generation apparatus to the information processing apparatus.

10. The controlling method according to claim 7, wherein the controlling method further causes the image generation apparatus to perform a combining step of combining the image data for printing and form data with each other.

11. The controlling method according to claim 7, wherein the image data for printing is data to be printed.

12. The controlling method according to claim 7, wherein

the fourth transmission step in the image generation apparatus transmits the identification information received from the information processing apparatus to the information management apparatus, and

the obtaining step in the image generation apparatus obtains the content related to the identification information from the information management apparatus.
